What is Muscular Dystrophy?

Muscular dystrophy is a group of disorders in which specific muscles of the body get weaker over time. Different kinds of muscular dystrophy affect people at different ages and affect different muscles.

Duchenne/Becker muscular dystrophy (DBMD) is the most common muscular dystrophy in children. DBMD affects about 1 out of every 3,500 to 5,000 boys. Girls rarely have DBMD. Of the more than 4 million births in the United States each year, about 400 to 600 are children with DBMD. The Centers for Disease Control and Prevention is working on a number of projects related to DBMD, including MD STAR*net*.

What's happening in my state?

In Iowa, CDC is working with the Iowa Department of Public Health and the University of Iowa to create a registry and monitor the health of children with DBMD.

CDC is also working with researchers at the University of Iowa to identify the needs of families with DBMD. The researchers will invite families to participate by telephone or in-person interviews to learn more about their needs related to muscular dystrophy. Eligible family members include young men with DBMD who are older than 14 years of age, and their parents, brothers, and sisters.

The goals of the Iowa project are to:

- Identify the major needs of individuals and families affected by DBMD.
- Identify factors that affect the availability of services and resources for families.
- Determine how the diagnosis of DBMD affects individuals and their families.
- Determine family members' opinions about screening all children for muscular dystrophy before symptoms are manifested.

For further information contact:

What is MD STARnet?

MD STAR*net*, the Muscular Dystrophy Surveillance Tracking and Research Network, is a program set up in several states to identify all children with DBMD.

What are the expected benefits of MD STAR*net*?

Because MD STAR*net* is an ongoing activity, it will provide better estimates of the number of people with DBMD over time. It will describe the health and service needs of people with DBMD and their families, which in turn will allow communities to provide better services, resources, and support. Ultimately, MD STAR*net* aims to improve the health and quality of life of all families with DBMD.

Who is involved in MD STARnet?

Currently, CDC is working with Arizona, Colorado, Georgia, Iowa, and New York State on this project. Other states will be added as the project grows.

How does MD STARnet work?

Children with DBMD will be identified using information gathered from many different sources, such as clinic medical records and hospital records. Public health scientists will collect information from these sources to keep track of each child's health care and changes over time. Families will also be asked to take part in interviews with researchers to gather information related to DBMD that might not be found in the medical records.

All of the data collected will be pooled anonymously (without names) to answer questions such as:

- How common is DBMD?
- Is it equally common in different racial and ethnic groups?
- What are the early signs and symptoms of DBMD?
- Do things such as the type of care received or the type of gene changes affect the severity or course of DBMD?
- What health care-related services, medical and social, are families receiving?
- Does health care vary in different areas? Do different populations receive different care?
